Does the Minimum Wage Reduce Inequality? Current vs Lifetime Perspectives

Minimum wages (MW) can strongly compress current earnings inequality, but do individual gains to low-wage workers persist over time, quickly dissipate or come at the expense of lower future earnings? Using Portuguese administrative data on all private-sector employment, I study a permanent 16.2% real increase in the national MW from 2006 to 2010 followed by a plateau until 2014. The reform generated strong current wage and earnings gains, but these relatively quickly dissipated over time. This dissipation is unlikely to be explained by adverse effects on employment, hours, or switching to different career paths. Instead, workers rapidly grow out of minimum-wage exposure and spend only a small fraction of their working lives near the floor. To extrapolate beyond the eight-year empirical horizon and get the policy's lifetime incidence, I estimate a statistical wage process which embeds a minimum wage. Workers at the bottom of the current-wage distribution receive the full 16.2% increase, whereas those with the lowest lifetime earnings gain 7.3% on average. Finally, income mobility can weaken the lifetime equity motive without lowering the optimal minimum wage when workers cannot self-insure, as the policy also provides insurance against low-income periods.

Working Papers

Decomposing Changes in Income Mobility

An economy's income mobility can change substantially over time. However, a substantial decline in population income mobility may either be the result of a decline in mobility within population subgroups, or of a growing share of population subgroups that are less mobile, such as women and older workers. This paper offers an exact decomposition of changes in mobility over time. Population mobility is not a simple weighted average of subgroup mobilities. As a result, beyond compositional dynamics in the labor force, the dynamics of inequality and of between-group gaps also matter for aggregate population mobility. I apply the decomposition to Portugal, an economy whose income mobility declined between 1986 and 2019 and which displays considerable heterogeneity in mobility across groups, using administrative data on the universe of private-sector workers. Population income mobility fell by around 10 percent over the period. No single grouping of workers tells the

story on its own: only within fine-grained groups, such as workers of the same age and education, does churning stay flat, revealing that the decline is driven by structural shifts between groups instead.

Greenfield Urban Planning (Submitted)
with Vernon Henderson, Guy Michaels, Martina Manara and Tanner Regan, 2026

Urban planning shapes cities, demarcating property rights and mitigating coordination failures, but its rigidities constrain market-driven development. In developing country cities, characterized by rapid growth and urban informality, greenfield urban planning, if done well, creates value. We develop a framework for analyzing how planning choices affect land and individual-level outcomes and, thus, the magnitude and distribution of this value. We study Tanzania's flagship "20,000 Plots" project in Dar es Salaam, which partitioned peri-urban land into over 36,000 formal residential plots. Using administrative records, satellite imagery, and primary surveys, we estimate causal effects of planning decisions using highly local within-neighborhood variation and spatial regression discontinuities, and we develop and estimate a dynamic structural model. We find that the price per square meter falls with plot size (elasticity of -0.5) within project neighborhoods. The model yields a sufficient statistic for planners: inefficient allocations have decreasing price per square meter with plot size. Model counterfactuals indicate that welfare maximization would increase the relative supply of small plots and spread gains more evenly, though still attracting mostly higher-income households. Land value maximization would, in contrast, have many fewer plots overall, focused even more on higher-income households. Extending the current project would generate large net gains, reflecting model shadow values well above cost. Land values are roughly twice those in nearby informal areas conditional on plot size, mostly due to secure property rights and road access.

Will the Economic Impact of COVID-19 Persist? Prognosis from 21st Century Pandemics (Pre-PhD)
with Johannes Emmerling, Davide Furceri, Prakash Loungani, Jonathan D. Ostry, Pietro Pizzuto and Massimo Tavoni
IMF Working Paper 2021/119

COVID-19 has had a disruptive economic impact in 2020, but how long its impact will persist remains unclear. We offer a prognosis based on an analysis of the effects of five previous major epidemics in this century. We find that these pandemics led to significant and persistent reductions in disposable income, along with increases in unemployment, income inequality and public debt-to-GDP ratios. Energy use and CO_2 emissions dropped, but mostly because of the persistent decline in the level of economic activity rather than structural changes in the energy sector. Applying our empirical estimates to project the impact of COVID-19, we foresee significant scarring in economic performance and income distribution through 2025, which could be associated with an increase in poverty of about 75 million people. Policy responses more effective than those in the past would be required to forestall these outcomes.
